

Monte Carlo Sampling - 3

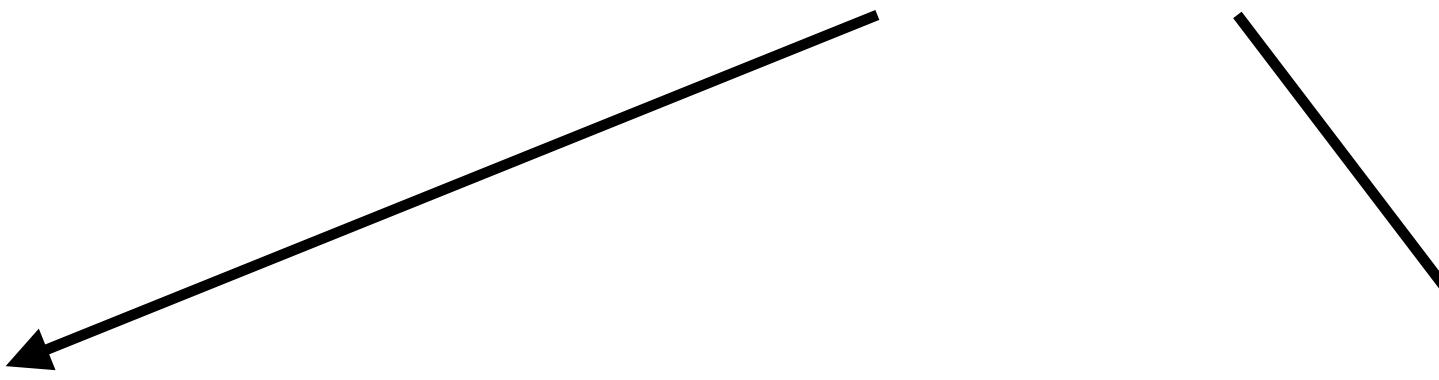

Wu and Frazier 2017

Reparameterization Trick

Reparameterization expresses the new GP mean with the included x^{n+1} data point $\mu_y^{n+1}(x)$ using the old GP mean $\mu_y^n(x)$

$$\mu_y^{n+1}(x) = \mu_y^n(x) + \tilde{\sigma}_y^n(x, x^{n+1}) Z_y, \quad Z_y \sim \mathcal{N}(0, 1),$$

Reparameterized covariance coefficient of x, x^{n+1}

$$\tilde{\sigma}_y^n(x, x^{n+1}) = \frac{k_y^n(x, x^{n+1})}{\sqrt{k_y^n(x^{n+1}, x^{n+1}) + \sigma_\epsilon^2}}$$

Introducess randomness to GP posterior sampling

Notice the new posterior mean is a linear function of Z_y
